

ABSTRACT

A system and method for upgrading software application is disclosed. The system provides a profile upgrade utility that generates a profile of desired application upgrades based upon information provided from a user. In operation, a user may provide a description of modules for upgrade, along with any associated components and a description of the module location. Using this information, the system generates a profile of the desired upgrade. The upgrade profile is then converted to a text file and uploaded to an import/export utility that retrieves the requested upgrades.
